Write 150–250 words. State the question, the method, the result, and why it matters — in that order. Do not cite, do not define new symbols, do not promise what the paper does not deliver. Example: *We ask whether [question]. We show that [method] gives [result]. This implies [consequence] for [field].* Replace this whole paragraph with your abstract.

5 Conclusion

Introduction

Start with the problem, not with the history of the field[1–3]. One paragraph: what is unknown? One paragraph: why does it matter? One paragraph: what do you do about it?

This template shows the format of every article in *Human Life Programming Language* (HLPL)[4]. It is also a short guide to the journal's scope and format, so that authors can see both at once: the layout on this page, and the rules in Sections 2–3.

HLPL is an overlay journal for the Physics of Meaning. It publishes work that treats meaning, language, cognition, and life as physical phenomena: measurable, modellable, and testable[5, 6]. A paper in HLPL must do more than argue. It must define its terms, state a claim that could be wrong, and show evidence, a model, or a proof that bears on that claim.

How to use this template

Delete the bracketed placeholders and the filler paragraphs, keep the commands[7, 8]. Do not change the margins, the fonts, the column layout, or the title block. If you add a package, add it after `\usepackage{hlpl}` and check that the document still compiles twice with no warnings about overfull boxes.

What a good first paragraph does

A good first paragraph names the phenomenon, the gap, and the contribution, in that order. Compare: "Language is important" (no gap, no contribution) with "Dependency length in 37 languages is shorter than chance, but no variational principle predicts by how much. We derive that bound from least action and test it." The second sentence can be checked. Aim for sentences that can be checked.

Journal Scope

What HLPL publishes

HLPL publishes research on meaning as a physical process. Topics include, but are not limited to:

- Gravitational physics, encompassing general relativity, alternative theories of gravity, and loop quantum gravity;
- The physics of meaning, information, and cognition;
- Language as a physical system: production, structure, change, and cost;
- Brain-time, neuro-time, and word-time; time, order, and memory in living systems;
- Variational principles, least action, and geodesics in cognitive and linguistic systems;
- Quantitative, computational, and formal models of language and mind, tested against data;
- The interface of physics, linguistics, neuroscience, and the study of life.

A paper may be theoretical, experimental, computational, or a synthesis, provided it is precise about its claims and its evidence.

What HLPL does not publish

HLPL does not publish purely speculative essays, summaries without a new claim, or work that uses physics terms as metaphors without a model. "The brain is like a quantum computer" is not a result. "Under assumptions A–C, the model predicts X; in corpus Y we measure X ± error" is a result, even if the result is negative. Negative results, replications, and corrections are welcome when they are precise.

Article types

Table 1 lists the article types. If you are unsure which type fits your paper, choose the closest one and say so in your cover note. The editors may reclassify a paper during review; reclassification is not a rejection.

Journal Format

Table 1: Article types in HLPL. Lengths are guidelines, excluding references.

Type	Typical length	Peer review
Research Article	4,000–8,000 words	Single-blind, 2+ reviewers
Short Communication	1,500–3,000 words	Single-blind, 1+ reviewer
Review / Synthesis	6,000–10,000 words	Single-blind, 2+ reviewers
Comment / Reply	800–2,000 words	Editorial + 1 reviewer
Methods / Code Note	1,500–4,000 words	Single-blind, 1+ reviewer

Manuscript structure

Use this order: title, authors, affiliations, abstract, keywords, introduction, main sections, discussion or conclusion, acknowledgments, data and code availability, references. Put long derivations, extra tables, and code listings in an appendix after the references, not in footnotes. Number sections as in this template: `\section`, `\subsection`, `\subsubsection`.

Length, language, and files

Write in clear English. Define every abbreviation at first use. Submit one `.tex` file (this template), the `hlpl.sty` file, and every figure as a separate PDF or PNG file. Name figures `fig1.pdf`, `fig2.pdf`, and so on. Do not paste figures into the text as screenshots of text: a figure must stay readable when printed in black and white and when enlarged to 200%.

Figures

Figure 1 is a placeholder figure. Replace it with your own figure, keep the caption below the figure, and refer to every figure in the text before it appears. A caption must let the reader understand the figure without reading the paper: state what is plotted, what the axes are, and what the reader should notice.

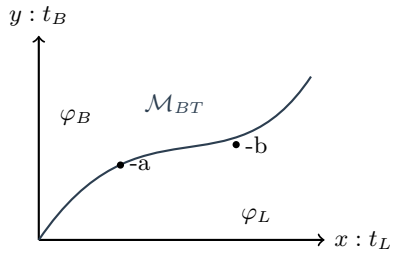

Figure 1: Replace this drawing with your own figure. Caption: what is shown, what the axes mean, and what the reader should notice.

Equations

Number every equation you refer to. Define every symbol. Equation (1) is a placeholder: replace it with your own central equation, and then explain it in words directly below it. An equation without a sentence explaining it does not count as an explanation.

$$S_{\mathrm{cog}}[t] = \int_{t_0}^{t_1} L_{\mathrm{cog}}\big(q(t), \dot{q}(t), t\big)\, dt, \qquad \delta S_{\mathrm{cog}} = 0 \tag{1}$$

where $[q(t)]$ is [your variable], $[L_{\mathrm{cog}}]$ is [your Lagrangian or cost], and $[t]$ is [your time variable]. The condition $\delta S_{\mathrm{cog}} = 0$ means [state in one sentence what your model predicts]. If your paper has no equation, delete this subsection and say so in your cover note; a paper is not required to have equations, but it is required to have checkable claims.

Tables

Table 2 is a placeholder table. Put the caption above the table, use `booktabs` rules (`\toprule`, `\midrule`, `\bottomrule`), and do not use vertical lines. Every number in a table must also be explained in the text or in the table note. If a reader cannot tell what a column means, the table is not finished.

Table 2: Replace the numbers with your own results.

Dataset	n	Measure	Result
Corpus A	986	mean	0.42 ± 0.03
Corpus B	37	mean	0.38 ± 0.05
Control	37	mean	0.51 ± 0.04

Citations and references

Cite with `\citep{heneka2026,hell2026}` for parenthetical citations and `\citet{heneka2026}` for narrative citations. Example: dependency length minimization is well documented [3], and Heneka et al. [1] report the lexical pattern. List every cited work in the References, and cite every listed work in the text. Use DOIs where available. Do not cite work you have not read.

Data, code, and reproducibility

State where the data and code are. The minimum is a link to a public repository (Zenodo, GitHub, or equivalent) plus the version or commit used. If data cannot be shared, say why, in one sentence. HLPL is an overlay journal archived on Zenodo: each article receives a DOI, and the published version is the version of record.

Discussion

What did you find? What does it rule out? What is still unknown? Do not repeat the results; interpret them. Name the strongest objection to your claim and answer it. If you cannot answer it, say so: a stated limitation is stronger than a hidden one.

Replace this paragraph with your own text. Keep one idea per paragraph, define every symbol before you use it, and give the reader a reason to read the next paragraph. If a sentence does not change what the reader believes, delete it. Placeholder text is here only to show the layout, the line spacing, and the length of a typical page in this two-column format. Do not submit placeholder text.

Conclusion

One paragraph: the claim, the evidence, the consequence. A reader who reads only the abstract and the conclusion should know what you showed and why it matters.

Acknowledgments

Funding, help, and tools. Example: “Independent research, no external funding. The author thanks [names] for [specific help]. AI tools were used for [editing / coding / literature search] and the author checked all outputs.”
